Table S1. Estimates of handling time h (s) and how they relate to shell length (L in mm; shell height in case of *Hydrobia*). Bivalve estimates are taken from Piersma *et al.* (1995), estimates for *Hydrobia* stem from Van Gils *et al.* (2005). As assumed by Zwarts and Blomert (1992) and Van Gils *et al.* (2005), handling burrowed bivalves lasts at least 2 seconds because of the time required to take them out of the mud.

Prey species	Size class	Handling time h (s)
<i>Macoma & Scrobicularia</i>	≤ 9 mm	2
	10-18 mm	$0.0233 * L^2$
<i>Cerastoderma</i>	≤ 7 mm	2
	8-16 mm	$0.0344 * L^2$
<i>Hydrobia</i>	0-8 mm	0.33

Table S2. Estimates of searching efficiency a ($\text{m}^2 \text{s}^{-1}$), taken from Piersma *et al.* (1995) in case of *Macoma* and *Cerastoderma*. Searching efficiencies for *Scrobicularia* and *Hydrobia* were assumed to be similar to those for *Macoma*.

Prey type	Searching efficiency a ($\text{m}^2 \text{s}^{-1}$)
<i>Macoma</i> & <i>Scrobicularia</i>	0.00052
<i>Cerastoderma</i>	0.00064
<i>Hydrobia</i>	0.00052

Table S3. Densities D (m^{-2}) and shell lengths (mm; or heights in case of *Hydrobia*) of available prey within 500 m of dropping samples, averaged (\pm SD) per species per site across the means per dropping sample.

Area	Sites	N dropping samples	Prey species	Length class (mm) Mean \pm SD	Density D (m^{-2}) Mean \pm SD
Dutch Wadden Sea					
	Engelsmanplaat	20			
			<i>Macoma</i>	10.3 \pm 1.6	379 \pm 204

Oléron	9	<i>Macoma</i>	12.4 ± 1.9	96 ± 66
		<i>Cerastoderma</i>	-	-
		<i>Hydrobia</i>	3.1 ± 1.6	$5,515 \pm 1,017$
		<i>Scrobicularia</i>	6.3 ± 2.3	498 ± 363
		<i>Cerastoderma</i>	10.7 ± 2.0	90 ± 51
		<i>Hydrobia</i>	3.8 ± 0.9	$15,888 \pm 6,151$

Table S4. Observed \log_{10} - \log_{10} relationships for flesh mass e (mg ash-free dry mass) and ballast mass k (mg dry mass of shell) as a function of shell length (mm; or shell height in case of *Hydrobia*). N gives the number of individual mollusks measured (which represents all individuals within a single site; we had to pool all benthos samples within single sites to get a large enough dataset to be able to perform these allometric regressions).

Fig. S1. Parameter-sensitivity of Mean Euclidean distances $E_{obs-pred}$ (\pm SE) between the observed diet and the predicted DRM-diet (dots), the CM-diet (triangles), and the NSM-diet (crosses) for each prey species. Prey-specific parameters are from top to bottom: handling time h , energy content e (ash-free dry mass flesh), ballast mass k (dry mass of shell) and encounter rate λ (being the product of searching efficiency a and density D). Vertical dashed lines denote the parameter values as used in the tested models. Note that *Scrobicularia* replaces *Macoma* at the Oléron site.
